PROJECTED TOTAL POPULATION

OF

CALIFORNIA COUNTIES

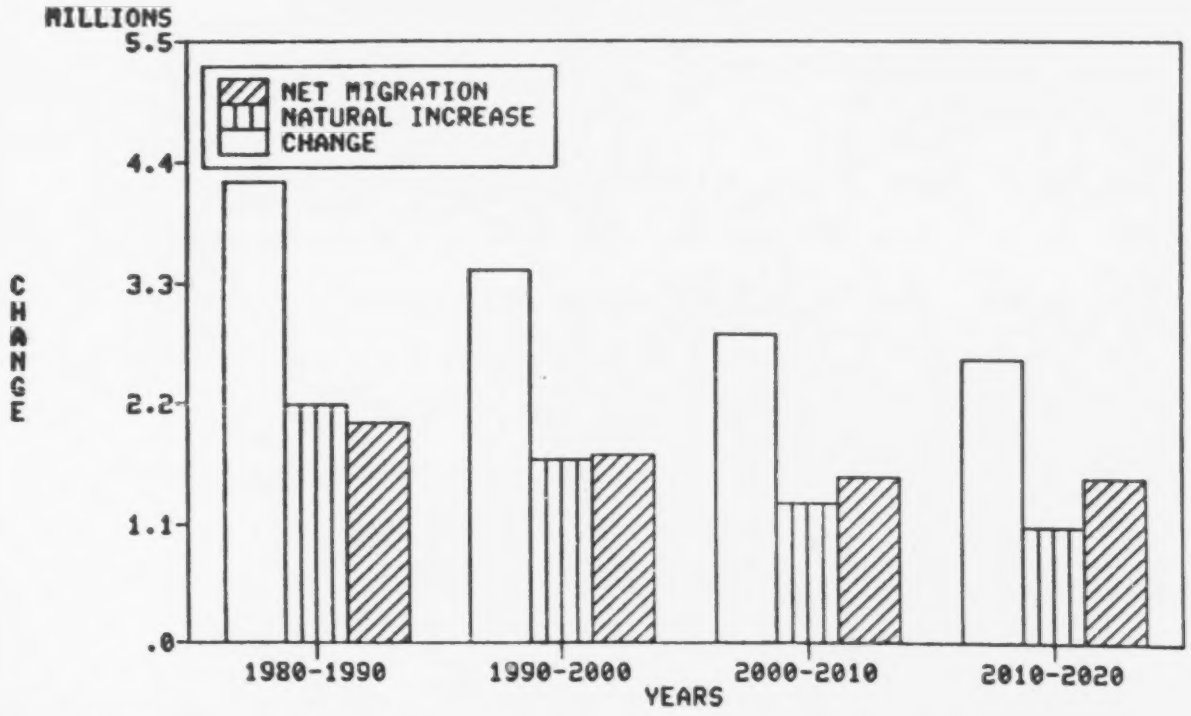
POPULATION RESEARCH
LINDA GAGE, CHIEF
MARY SCHLOSSER,
RESEARCH MANAGER
(916) 322-4651

Implication of the Population Projections

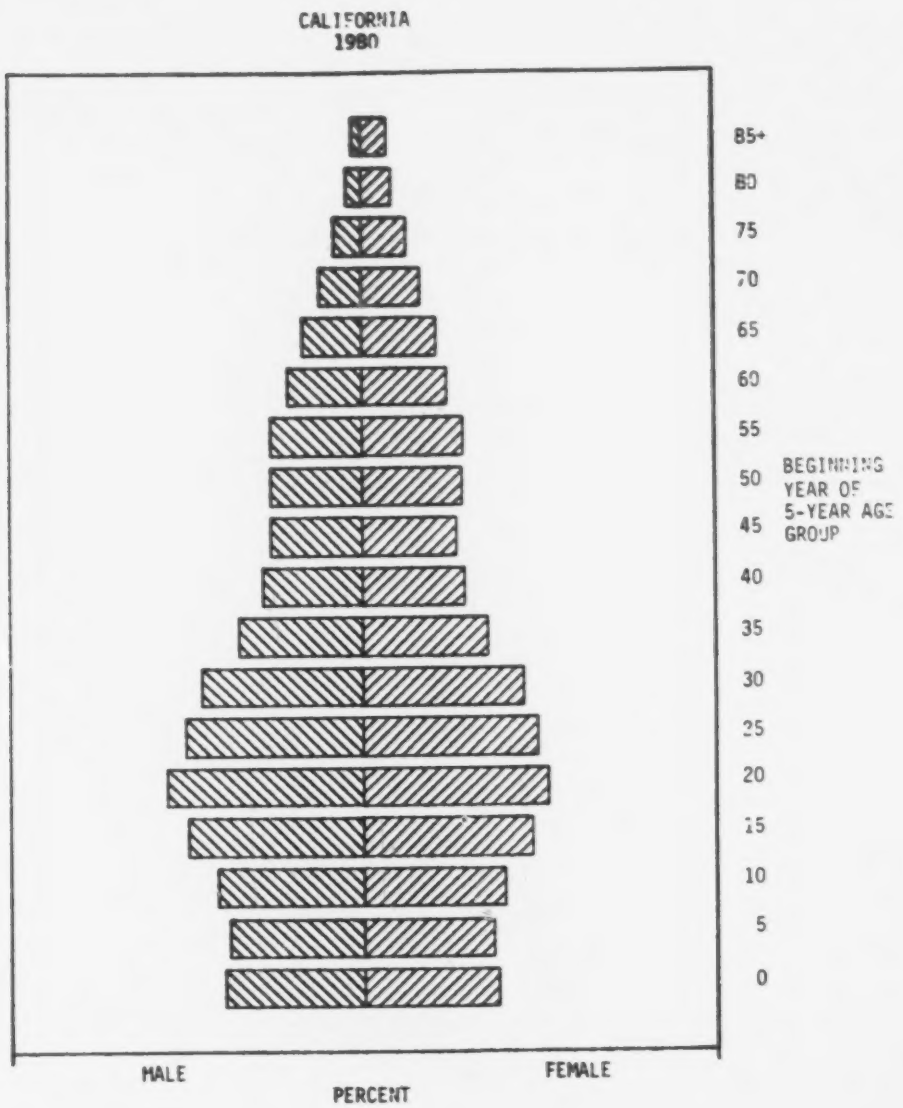
If current trends continue for the next 40 years, California's population will reach nearly 37 million. San Diego County will surpass Orange County and become the second most populous in the State. Ventura will become one of the 10 most inhabited counties and San Francisco will drop from number eight to number 12 in ranking. In addition, the Central Valley counties will increase their proportion of the State while the Bay Area will become a smaller percent.

The State as a whole will gain over 13 million people. About half the increase over the time period will be due to natural increase, births minus deaths, and about half due to net migration. However over time both components of population change will slow, as the State ages. Southern California will experience the largest absolute increase, over 7 million; but at the same time, the Sierra Nevada Foothill counties will record a 188 percent gain. Over the entire 40-year period Calaveras County will register the highest percent increase and San Diego the greatest absolute growth. San Francisco will be the only area to decline over the projection period. From 1980 to 1990 Nevada will be the fastest growing county in the State, from 1990 to 2000 Calaveras county takes the lead and after the year 2000 Mono County experiences the largest percent increases.

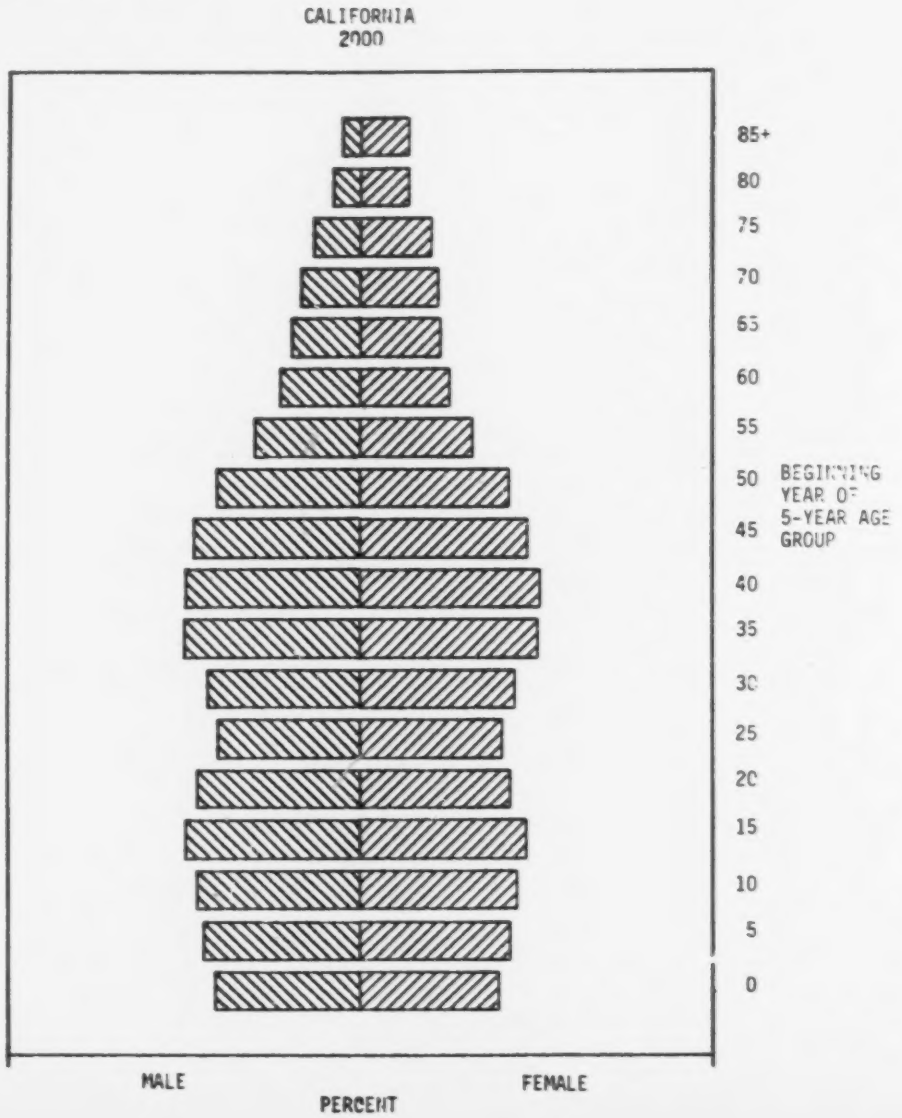
CALIFORNIA
PROJECTED COMPONENTS OF POPULATION CHANGE
1980-2020



The median age in the State rises from the 1980 figure of 29.9 to 35.8 in the year 2000 to 38.1 in 2020. This increase represents the aging of the baby boom cohort. Through the 80's and into the 90's Kings County will have the youngest median age and Lake County the oldest. However, after the year 2000 Mono County will have the youngest population and Marin the oldest.



The percent of children in the primary school ages will remain fairly stable during the projection period. This is due to relatively stable fertility on a statewide basis during the projection period. In 1980 Imperial County had the highest percent of children 5 to 13 years old. By the year 2000 it will share that distinction with Modoc County. The percent of children in the secondary school ages will drop almost a point between 1980 and 2000. This reflects the low fertility rates of the 1970's. In 1980 Imperial County also had the largest percent of children in the 14-17 age group but by the year 2000, Tulare County has the greatest proportion.



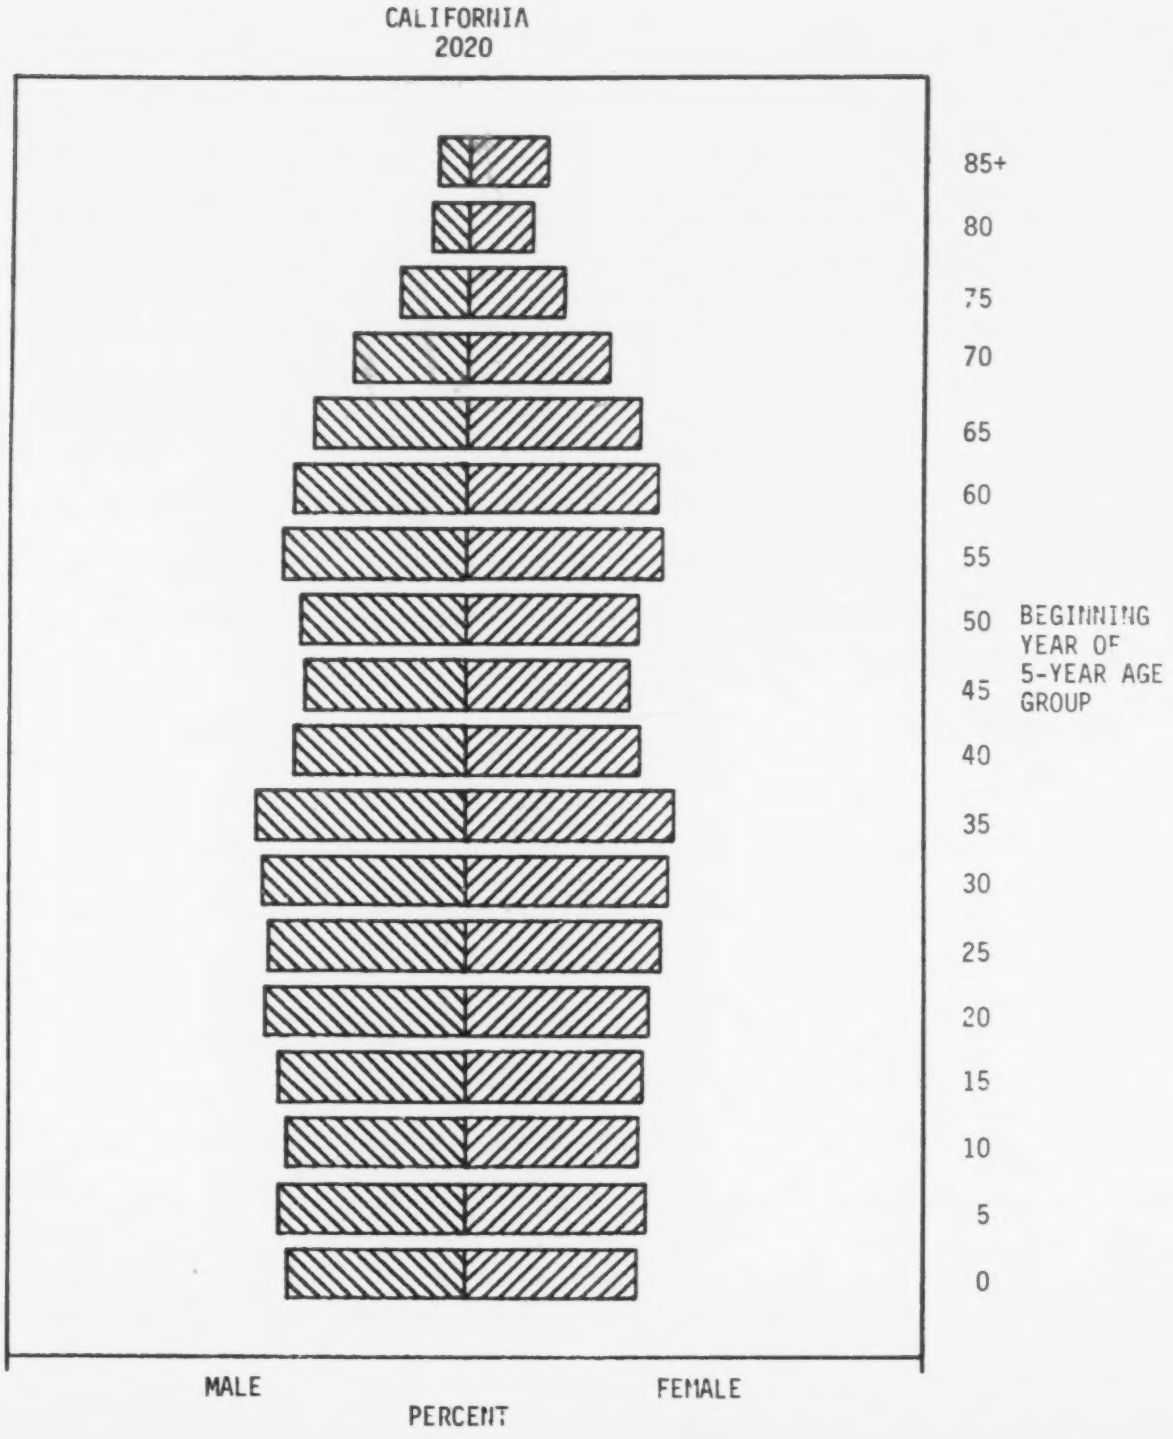
On a statewide basis 18 and 19 year olds will drop about a half a percent between 1980 and 2000. This age group is generally considered labor force entrants. A drop in this cohort futher illustrates the low fertility of the 1970's. Throughout the projection period Yolo County will have the highest proportion of people in this age group. The University of California at Davis accounts for this high percentage. Young adults, the people who form new households, will decline as a proportion of the total population between 1980 and 2000. The drop is caused by the baby boom cohort moving out of this age group. Mono County will continue to have the largest proportion of 25 to 34 year olds throughout the forecast period.

The older population will increase in Califoria during the next 40 years. Between 1980 and 2000 the percent statewide of those 65 and over will increase by two. The proportion of counties with 12 percent or more over the age of 64 will rise from 20 to 35 percent. Lake County will continue to be the county to have the largest proportion of its population 65 and over. The percent of people over 85 will nearly double between now and 2000. Today Napa County has the largest proportion 85 and over. By the year 2000 Inyo County will have the greatest percentage.

In addition, a couple of other interesting implications result from the population projections. The median age of mothers at birth increases from 25.9 in 1982 to 26.4 in 2000. Life expectancy rises from 74.7 to 76.8 in 2000 and then increases to 77.9 in 2020. To futher break this down, female life expectancy rises from 78.3 in 1980 to 80.6 in 2020. At the same time, male life expectancy increases from 71.1 in 1980 to 73.3 in 2020.

As these trends show, the characteristics and behavior of the

population in California will change over time. By analyzing demographic trends, we can better plan for tomorrow.



TECHNICAL NOTES

Introduction

The Department of Finance uses a baseline cohort component method of projecting population by age and sex. A baseline projection assumes no more than current intervention. Every person has the right to migrate where they choose and no major natural catastrophes or war will befall the State or the nation. A cohort component method traces people having a common year of birth throughout their lives. As each year passes, cohorts change due to mortality and migration; and the fertility of women of child bearing age creates new cohorts.

Basic Civilian Population

The basic civilian population precludes special populations (military personnel and their dependents, college students, and the institutionalized). Active military personnel and their dependents are excluded from the population. College students and persons institutionalized in State mental hospitals, juvenile and adult correctional facilities are allocated to their county of origin. The 1980 census serves as the benchmark. Data were obtained for each county by sex and single year of age. The special populations are subtracted from the census benchmark.

The military are estimated using annual reports from the United States Bureau of the Census adjusted to the 1980

decennial enumeration. The sex of the military are estimated based on national proportions and a telephone survey of the largest military bases in California. Age estimates are based on the 1970 census. Military dependents by age and sex are estimated using data from the armed forces for on-base housing and the 1970 census for those who live off-base.

The definition of college students is limited to those students 29 years and younger, enrolled full-time. Data are obtained from annual reports of fall enrollment provided by the University of California and the California State University and College systems. Data for private colleges are obtained from administrative records prepared for the Federal government.

Department of Corrections, California Youth Authority, Department of Developmental Services, and Department of Mental Health provide data on institutionalized populations. Administrative records are controlled to 1980 census data.

Survival, Fertility, and Migration Rates

Survival rates are developed using deaths by age for the decade of the 1970s from the Department of Health Services . Mortality rates are computed using the average of 1979 and 1980 deaths. This compensates for any unusual occurrences that may have taken place in any one year such as a flu epidemic. The basic civilian population serves as the base

to compute the mortality rates which are then converted to survival rates. These rates are derived for single years of age by sex and represent a one-year rate.

The age specific fertility rates for 5-year cohorts are developed for the female population aged 15 to 44 years. Births by age of mother for the most recent year available are used. Births to women aged less than 15 and over 44 years are added to the youngest and oldest cohorts respectively. Again, the basic civilian is used as the base in the rate computation.

To compute migration rates a basic civilian population for 1970 was estimated and survived to 1980. Births were added to create new cohorts throughout the decade. The 1980 basic civilian population was further adjusted to remove Southeast Asian Refugees whose immigration was administratively determined. The survived 1970 basic civilian population was compared to the 1980 basic civilian population and the differences are assumed to be migration. Since it is a residual category the migration estimate also includes any errors resulting from the survival and fertility rates. The estimates of migration by age and sex are converted to annual migration rates and a percentage male. These rates are smoothed based on the 5-year cohort rates.

Assumptions

The 1977 Series E-150 assumed that a local area's average lifetime births to a woman would approach the national assumption of 2.1. However, in 1980 the actual total

fertility rate for the nation was 1.8 compared to the Bureau's projected rate of 1.9. In addition, the Census Bureau's survey of birth expectations showed a decline in the expected lifetime births to young women to under 2.0 for the first time. The survey results along with the negative effects on fertility of increased female labor force participation, older age of marriage and higher educational levels resulted in the Bureau's decision to lower the fertility assumption to 1.9. At the same time, the assumed mean age of childbearing in the national projections increases from 26.0 in 1981 to 26.5 in 2050.

Analysis demonstrates that the completed fertility rate for California has merged toward the national rate for the past 30 years and recently has followed United States trends closely. However, because California's race and ethnic makeup is different than the nation, we decided to merge the age specific fertility rates to one-half their current difference from the nation in 100 years. The Series E-150 merged to one-half the difference in 40 years. This merging process for the State as a whole increases the average age of childbearing from 25.9 in 1982 to 26.4 in the year 2000.

In the past, mortality trends have graphed like a staircase. Rapid declines in mortality due to medical breakthroughs are followed by periods of only slight declines. From 1940 to 1960 mortality dropped only slightly, but earlier in the century substantial increases in life expectancy resulted from the control of infectious diseases. The past couple of

decades have again resumed sharp declines in mortality rates. These improvements are apparently due to early detection and treatment of cardiovascular disease and changes in life style which have reduced death due to heart attacks and strokes. The most recent Federal projections assume an increase in life expectancy from 74.8 in 1982 to 79.6 in 2050. It should be noted that it is assumed life expectancy will increase only half as rapidly after 2005 as it did before then.

We are handling mortality rates in the same manner we are merging age specific fertility rates. County specific age and sex mortality rates will be merged to one-half their current difference from the national rates in 100 years. Again California's unique age and race make-up would mandate a longer period to merge to national assumptions.

Migration is the most volatile of the components of population change. When describing the characteristics of migrants into California it is useful to classify them into domestic and foreign. Domestic migration peaked in the 1950s, bottomed out in the early 1970s and has been on the increase since that time. Recently, California's net migration has consisted of about half domestic and half foreign.

Foreign migrants can be further classified as legal and illegal. During the late 1970s we estimated that nationally approximately 25 percent of all documented non-refugee migrants settled in California and about one-third of all

the Southeast Asian refugees come to California. Very little is know about illegal migrants although there has been a great deal of conjecture. We do not even know with any certainty the number living in California at the present time or any time previously. It has been Census Bureau policy not to ask legal status on their surveys or censuses. This makes it impossible to project their numbers.

An additional problem with trying to project migration is the difference in coverage between the 1970 census enumeration and the 1980 census count. Because our migration estimating technique is a residual method, differences in coverage between the censuses would show up in our net migration estimate. For this reason we relied heavily on migration estimates made prior to the 1980 census.

Because our projection is a baseline we assume net migration will follow recent trends. Our method has been to weight the most recent 2-year period and modify this trend into the future. We removed refugee immigration from the baseline because it is administratively determined. To the extent that illegal aliens are recorded by our current indicators -- for example school enrollment, driver licenses, and medicare -- undocumented migration is included as a portion of our net migration projections.

Using historical analysis, a weighted average, the most recent data available, and our best judgement we projected California net migration at an annual average of 167,000 out

to the year 2020. It is assumed that domestic net migration will continue at its current level. Foreign net migration will continue at a high level. Although the influx of Southeast Asian Refugees will slow, California will continue to receive many secondary migrants as refugees from other states move to California and as California refugees receive their citizenship they will apply to bring additional family members to this country. As time passes both domestic and foreign migration are expected to slow somewhat, returning to the levels of the late 1970s. This new level of migration is somewhat above the 150,000 projected in 1977 because it takes into account 1981 and 1982 net migration which averaged 229,000.

County migration assumptions were done in conjunction with local planners. During the course of annual city visits 48 percent of the counties were surveyed as to what they foresaw happening in their area in the next 20 years. Soon thereafter all counties and COGs (Councils of Governments) were sent a survey requesting what levels of migration they anticipated in the future. Accompanying the survey were statistics representing our best migration estimates for the past years. 64 percent of the counties and four of the COGs responded to this survey. After the survey results were tabulated an analysis was done by the department and preliminary migration assumptions by county were made.

Following this process meetings were held with 66 percent of the counties and all the major COGs to discuss these

migration assumptions. After these meetings the assumptions were reevaluated and controlled to the State total. This prompted further comments from 45 percent of the counties and 3 of the COGs. In order to make sure all local areas had an opportunity to respond a general meeting was also called and draft data sent to those who could not attend. Through this process virtually all counties and COGs had some input to the projection process. Finally information acquired at three public meetings held in Sacramento, San Francisco, and Los Angeles was considered and final assumptions were made.

Demographic Model

The basic civilian benchmark population is projected using the final assumptions. New cohorts are created by applying the fertility assumptions to the women in child bearing years. The population ages with time and sex/age specific survival rates are applied to the population at risk. In addition, the overall migration assumption is distributed using the assumed age/sex migration rates. The process is carried forward 40 years.

Projecting Special Populations

The special populations are projected, returned to the county of attendence/committment, and added to the basic civilian population. Age/sex composition of the special populations were developed by applying rates developed from the 1980 data to the local population. Control totals are obtained from the administering State department. The

military and their dependents were held constant throughout the projection period.

Meanwhile, the user is reminded that these numbers depict only one possible course of future population, one attempting to reflect recent trends in fertility, mortality and migration. They to not necessarily show what is most desirable.
